GB/04/2273

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

Notes

- a) If you need help to fill in this form or you have any questions, please contact the Patent Office on 08459 500505.
- b) Write your answers in capital letters using black ink or you may type them.
- c) If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- d) If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- e) Once you have filled in the form you must remember to sign and date it.
- f) For details of the fee and ways to pay please contact the Patent Office.

C892/H

Title: Powder dispenser

Field of invention

This invention relates to devices for dispensing powder such as talcum powder.

Background

It is known to package talcum powder in a rigid container having a dispensing nozzle at one end having a plurality of small holes therein through which powder can be dispensed by shaking the container, normally in a horizontal or inverted condition.

It is also known to package talcum powder in a flexible walled container also having a similar dispensing nozzle at one end through which powder can be forced by squeezing the flexible wall, whether inverted or upright.

A powder dispenser is described in US Patent Specification 4,730,751 in which a dip tube conveys powder to a discharge plug in a flexible walled container and a multicellular foam pad encases the lower end of the tube for effecting smooth and uniform movement, without clogging, of powder through the tube when the container is squeezed to discharge powder when the container is upright. The device includes air passages which allow air to pass directly to a mixing chamber in the plug and these can be covered by a similar foam pad to prevent clogging when discharging powder while the container is inverted.

Object of the invention

It is an object of the present invention to provide a modification to such powder dispensing containers and nozzles therefor, to allow more controlled dispensing of powder therefrom, and an improved method of discharging powder therefrom, without the need for a mixing

chamber in the discharge nozzle (plug) and without the need for a dip tube to convey powder to the discharge nozzle when discharge is to be effected with the container in an upright condition.

Summary of the invention

According to one aspect of the present invention within or associated with a powder dispensing nozzle of the type having one or more small holes through which powder can be ejected and located in the wall of a container partially filled with the powder which can be dispensed either by shaking or by air pressure caused by squeezing the container, there is provided an intermediate powder reservoir on or in which some of the powder within the container becomes lodged by inverting or shaking the container, such that on subsequently shaking or squeezing the container, to dispense powder therefrom, at least some of the powder lodging in or on the intermediate reservoir is caused to pass through the hole or holes in the nozzle, the intermediate reservoir serving to impede the passage of the remainder of the powder in the container to the nozzle openings if the container is inverted during shaking or squeezing, so that in general during each discharge action, only the powder in or on the intermediate reservoir will exit via the nozzle.

The action of shaking or squeezing the container not only causes powder in the intermediate reservoir to leave the container via the nozzle but can also cause other of the powder in the container to replace at least some of the powder that has left the intermediate reservoir, so that the latter is at least partially replenished during each discharge action and is left ready to discharge another quantity of powder via the nozzle with the next shake or squeeze of the container. Otherwise the reservoir is replenished by inverting the container briefly.

In one embodiment the reservoir can be likened to, and comprise a filter inserted in the neck immediately below the end nozzle of a plastic powder puffer dispenser.

The filter reservoir may comprise a hollow tube the lower end of which is closed but having a plurality of small holes in at least the wall thereof and possible also the closed end, or the wall and base may be formed from a woven fabric, such as a woven wire or woven plastics mesh.

The available area of the hollow tube may be increased by corrugating the wall so as to form a concertina shape, as in a car air filter. Alternatively, moulded plastics modules or hairs may be included in the exterior design of the hollow tube, to increase the surface area to which powder can adhere.

Alternatively the filter may comprise a wad of mesh of the type used to construct pan or paint scourers.

The area of the perforated/apertured wall of the tube, or area of the woven mesh material making up the filter, determines the surface area available to entrap the powder. A larger area reservoir filter enables more powder to adhere thereto, or become embedded in the openings in its structure.

The invention is of particular application to dispensers having a flexible container wall and which are operated by squeezing the wall to force air and powder out. However it can be applied to rigid walled containers where dispensing is achieved by shaking, albeit basically where dispensing by shaking involves inverting the container to do so.

Thus the purpose of the intermediate reservoir is twofold. Firstly when for example squeezing so as to spray powder upwards, powder will have previously adhered to the filter (following for example a prior inversion or shake to charge it), which will be discharged as a single dose upwards. Without the reservoir, all the powder is in the base of the container and often only a negligible amount will be entrained into the airflow created by the act of squeezing the container, to be discharged upwards, unless a dip tube is used which can become clogged.

The second purpose is to limit the discharge from a nozzle in a container from which powder is dispensed downwardly from an inverted condition. Typically in order to limit discharge rates, the openings in a nozzle intended to discharge downwardly are made very small, but such small openings in the nozzle can easily become clogged when the container is inverted, and squeezed or shaken to dispense powder. By restricting access to the nozzle by the main body of powder in the container (by trapping only some of the powder in the intermediate reservoir from which it can be dispensed) and therefore the rate at which powder can be discharged from the bulk, larger nozzle openings can be employed thus reducing the risk of clogging. Without the intermediate reservoir, excessive amounts of powder can be discharged if the nozzle openings are increased so as to reduce the risk of clogging, unless a foam pad is employed at both ends of the dip tube, adding to the cost and complexity of the dispenser.

Where the container wall is flexible, the dispenser may be inverted or shaken to charge the reservoir, and then squeezed, preferably after rotating it so as to point generally upwardly. The surface area, and therefore powder retention properties, of the reservoir is selected to attract and retain a sufficient charge of powder to be available to be discharged upwards through the nozzle openings when the dispenser is squeezed.

When employed in a rigid walled container where dispensing is to be achieved by inverting and shaking, the intermediate reservoir now additionally serves to restrict the quantity of powder which can reach the nozzle when inverted.

Thus the use of an intermediate reservoir facilitates upward spraying, and can prevent nozzle clogging or excessive powder discharge, when discharging downwards, especially when ejecting powder by squeezing the container.

According to another aspect of the present invention a method of discharging powder such as talcum powder, from a flexible walled container having an outlet nozzle containing a plurality of small openings therein at one end and an intermediate reservoir in which powder can be retained internally of the openings in the nozzle for discharge through the

openings, comprises the steps of inverting the container to charge the intermediate reservoir, and thereafter squeezing the flexible container wall to pressurise the contents of the container and force powder in the intermediate reservoir through the openings in the outlet nozzle.

Preferably, prior to squeezing the container, it is rotated into an upright or near upright condition so that powder not retained by the intermediate reservoir falls away from the discharge end of the container so as not to be available to be discharged.

According to a further aspect of the present invention a method of discharging powder such as talcum powder from a rigid walled container having an outlet nozzle containing a plurality of small openings therein at one end and an intermediate reservoir in which powder can be retained internally of the openings in the nozzle for discharge through the openings, comprises the steps of inverting the container to charge the intermediate reservoir, and thereafter shaking the container to discharge the powder retained in the intermediate reservoir through the openings in the nozzle and simultaneously restrict the discharge of powder during each shake to that retained by the intermediate reservoir during the inversion or each previous shake of the container.

By flexible is intended a container wall which is resiliently deformable by squeezing and will revert to its normal shape when the squeezing force is removed.

The invention will now be described by way of example with reference to the accompanying drawings in which:

Fig 1 is a cut away section through a powder container fitted with a tubular intermediate powder reservoir, and

Fig 2 is a cut away section through a powder container fitted with a mesh which comprises an intermediate powder reservoir.

In Fig 1 a powder container 10 containing a main charge of powder such as talcum powder 12 is provided at its upper end with a dispensing nozzle 14 the upper end of which includes four holes 16 through which powder can be discharged. This is achieved by inverting and/or shaking the container 10. If the wall of the container is resiliently deformable, as by being made from a plastics material, the powder can be discharged upwardly or downwardly by squeezing the wall of the container, so as to force air and powder entrained therein, through the openings 16. If the container wall is not intended to be squeezed, discharge can be obtained by shaking the container in its inverted condition.

In accordance with the invention an intermediate powder reservoir is provided below the nozzle 14. In Fig 1 this comprises a hollow tubular member 18 fitted below the nozzle 14 so as to protrude inside the container. The wall of 18 includes a large number of small holes 19. Powder can become lodged in these holes if the container is shaken or inverted, and some powder may pass through the holes into the interior of the tube 18. Whether inside or merely lodged in the holes 19 in the wall of the tube, the latter serves as a reservoir for powder. When subsequently shaken or pressurised by squeezing the container wall, the powder inside the tubular reservoir (or merely in the holes 19) will be forced out through the holes 16.

Where it is not intended that the powder is to be discharged by squeezing the wall of the container, the holes 19 in the wall of the tubular reservoir 18 are preferably larger than if the powder is to be discharged under pressure, so that the act of inverting the container will cause powder to enter the reservoir 18, through the holes, and the act of subsequently shaking the container will cause the powder in 18 to exit by the holes 16.

The base 20 of the tubular reservoir 18 may be solid so that once powder has entered 18 through holes 19 there is little tendency for it to drop back into the main charge of powder in 10, under gravity, once the container has been stood upright on its base 20.

The cylindrical wall of the reservoir 18 may be formed from a woven fabric-like material such as woven wire mesh, the openings in the fabric or mesh comprising the holes 19, or from a solid material (metal or plastics) which is perforated by small holes 19.

In order to reduce the chance of powder leaving the container from the tube 18 and falling back into the main charge of powder 12, the thickness of the wall may be at least equal to (and preferably may be twice or three times) the diameter of the holes in the tube wall. Alternatively, where the holes are openings in an otherwise solid wall, a hollow tubular protrusion may surround each hole on the inside of the tube 18 so as to make it less likely for powder particles inside the tube to leave via the holes.

Where the holes are protected internally by tubular protrusions, the base of the tube 18 (which is otherwise preferably solid) may also be formed with holes, since the upstanding tubular protrusions will prevent powder which has built up in the base of the tube 18 from falling out through the holes at least until the depth of powder in the tube 18 is greater than the internal height of the protrusions.

An alternative design of reservoir is shown in Fig 2, where items which are similar to those shown in Fig 1 are denoted by the same reference numerals.

Here item 18 is replaced by a wad of plastic mesh 22 similar to a pan scourer. The act of shaking or inverting the container 10 will cause powder to become trapped in the mesh for subsequent discharge, either when shaken again or if the container wall is squeezed.

Where shaking is employed to charge the reservoir such as 18 or 22, it is preferable to cover the openings 16 with the hand or with a cap such as 24, which is removed before the container is subsequently shaken or squeezed to discharge the trapped powder through the holes 16.

Although four holes 16 are shown, it is to be understood that irrespective of the design of the intermediate reservoir any number of holes can be employed, either more or less, and a nozzle having only one hole can be used.

Although not shown where the reservoir 18 is moulded from plastics material, spikes of hairs which may be integrally formed by moulding from plastics material, are formed on the surface of the reservoir (both inside and/or outside) to increase the surface area available on which powder can adhere, and/or the outer surface may include a grid or gauze or honeycomb-like structure, defining a plurality of openings (pigeon holes) in which powder can become trapped when the container is shaken, (or more preferably, inverted) prior to discharge.
